

CHAPTER 20

Introduction to Transaction Processing Concepts and Theory

Introduction

- Transaction
 - Describes local unit of database processing
- Transaction processing systems
 - Systems with large databases and hundreds of concurrent users
 - Require high availability and fast response time

 T_2 read_item(X); X := X + M; write_item(X);

20.1 Introduction to Transaction Processing

- Single-user DBMS
 - At most one user at a time can use the system
 - Example: home computer
- Multiuser DBMS
 - Many users can access the system (database) concurrently
 - Example: airline reservations system

Introduction to Transaction Processing (cont'd.)

- Multiprogramming
 - Allows operating system to execute multiple processes concurrently
 - Executes commands from one process, then suspends that process and executes commands from another process, etc.

Introduction to Transaction Processing (cont'd.)

- Interleaved processing
- Parallel processing
 - Processes C and D in figure below

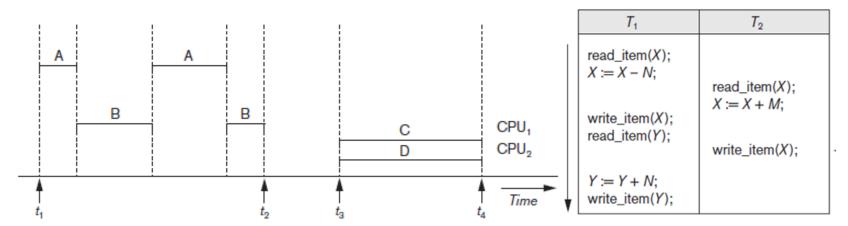

Figure 20.1 Interleaved processing versus parallel processing of concurrent transactions

Transactions

- Transaction: an executing program
 - Forms logical unit of database processing
- Begin and end transaction statements
 - Specify transaction boundaries
- Read-only transaction
- Read-write transaction

	<i>T</i> ₁	<i>T</i> ₂
me	read_item(X); X := X - N; write_item(X); read_item(Y);	read_item(X); X := X + M; write_item(X);
ļ	Y := Y + N; write_item(Y);	

Tir

Database Items

- Database represented as collection of named data items
- Size of a data item called its granularity
- Data item
 - Record
 - Disk block
 - Attribute value of a record
- Transaction processing concepts independent of item granularity

Read and Write Operations

- read_item(X)
 - Reads a database item named X into a program variable named X
 - Process includes finding the address of the disk block, and copying to and from a memory buffer
- write_item(X)
 - Writes the value of program variable X into the database item named X
 - Process includes finding the address of the disk block, copying to and from a memory buffer, and storing the updated disk block back to disk

```
T_1

read_item(X);

X := X - N;

write_item(X);

read_item(Y);

Y := Y + N;

write_item(Y);
```

Read and Write Operations (cont'd.)

- Read set of a transaction
 - Set of all items read
- Write set of a transaction
 - Set of all items written

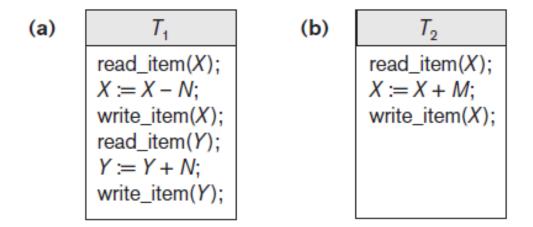

Figure 20.2 Two sample transactions (a) Transaction T1 (b) Transaction T2

Concurrency Control

- Transactions submitted by various users may execute concurrently
 - Access and update the same database items
 - Some form of concurrency control is needed
- The lost update problem
 - Occurs when two transactions that access the same database items have operations interleaved
 - Results in incorrect value of some database items

The Lost Update Problem

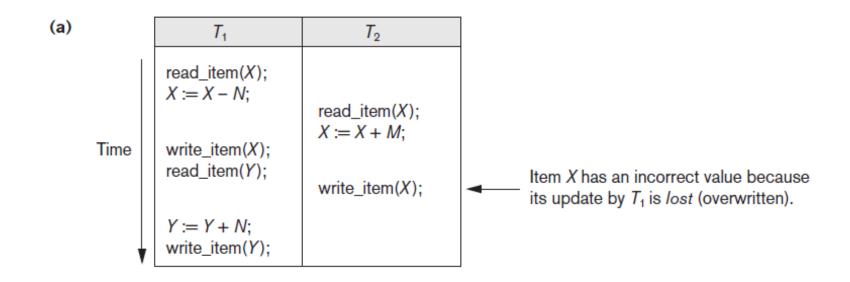

Figure 20.3 Some problems that occur when concurrent execution is uncontrolled (a) The lost update problem

The Temporary Update Problem

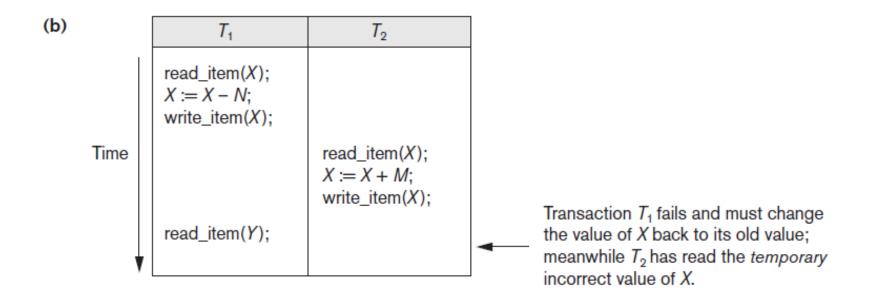

Figure 20.3 (cont'd.) Some problems that occur when concurrent execution is uncontrolled (b) The temporary update problem

The Incorrect Summary Problem

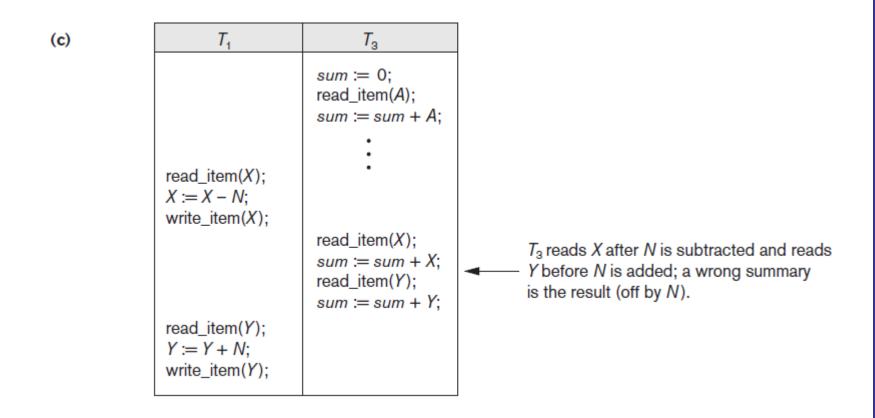

Figure 20.3 (cont'd.) Some problems that occur when concurrent execution is uncontrolled (c) The incorrect summary problem

The Unrepeatable Read Problem

- Transaction T reads the same item twice
- Value is changed by another transaction T' between the two reads
- T receives different values for the two reads of the same item

Why Recovery is Needed

- Committed transaction
 - Effect recorded permanently in the database
- Aborted transaction
 - Does not affect the database
- Types of transaction failures
 - Computer failure (system crash)
 - Transaction or system error
 - Local errors or exception conditions detected by the transaction

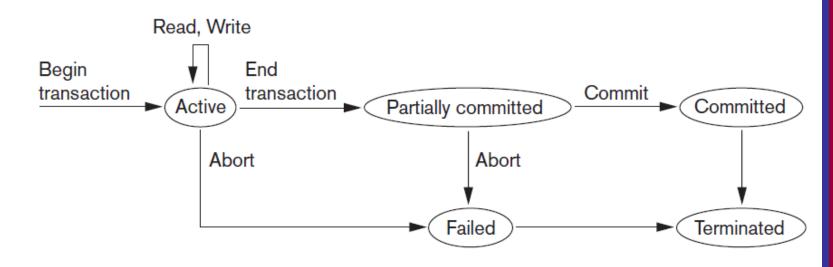

Why Recovery is Needed (cont'd.)

- Types of transaction failures (cont'd.)
 - Concurrency control enforcement
 - Disk failure
 - Physical problems or catastrophes
- System must keep sufficient information to recover quickly from the failure
 - Disk failure or other catastrophes have long recovery times

20.2 Transaction and System Concepts

- System must keep track of when each transaction starts, terminates, commits, and/or aborts
 - BEGIN_TRANSACTION
 - READ or WRITE
 - END_TRANSACTION
 - COMMIT_TRANSACTION
 - ROLLBACK (or ABORT)

Transaction and System Concepts (cont'd.)

	T_1	T_2
Time	read_item(X); X := X - N; write_item(X); read_item(Y); Y := Y + N; write_item(Y);	read_item(X); X := X + M; write_item(X);

Figure 20.4 State transition diagram illustrating the states for transaction execution

The System Log

- System log keeps track of transaction operations
- Sequential, append-only file
- Not affected by failure (except disk or catastrophic failure)
- Log buffer
 - Main memory buffer
 - When full, appended to end of log file on disk
- Log file is backed up periodically
- Undo and redo operations based on log possible

Commit Point of a Transaction

- Occurs when all operations that access the database have completed successfully
 - And effect of operations recorded in the log
- Transaction writes a commit record into the log
 - If system failure occurs, can search for transactions with recorded start_transaction but no commit record
- Force-writing the log buffer to disk
 - Writing log buffer to disk before transaction reaches commit point

20.3 Desirable Properties of Transactions

ACID properties

- Atomicity
 - Transaction performed in its entirety or not at all
- Consistency preservation
 - Takes database from one consistent state to another
- Isolation
 - Not interfered with by other transactions
- Durability or permanency
 - Changes must persist in the database

 $T_1 \qquad T_2$ $read_item(X);$ X := X - N; $read_item(X);$ X := X + M; $read_item(X);$ X := X + M; x := X + M

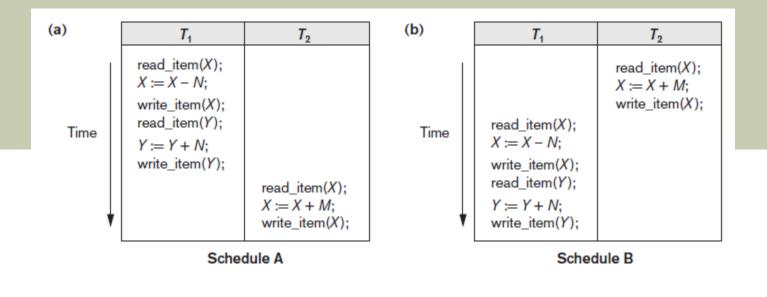

Time

20.4 Characterizing Schedules Based on Recoverability

- Schedule or history
 - Order of execution of operations from all transactions
 - Operations from different transactions can be interleaved in the schedule
- Total ordering of operations in a schedule
 - For any two operations in the schedule, one must occur before the other

20.5 Characterizing Schedules Based on Serializability

- Serializable schedules
 - Always considered to be correct when concurrent transactions are executing
 - Places simultaneous transactions in series
 - Transaction T₁ before T₂, or vice versa

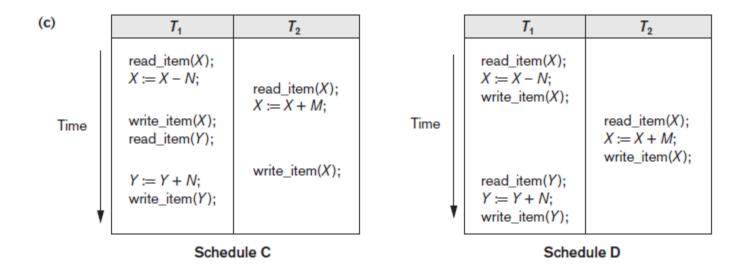

Figure 20.5 Examples of serial and nonserial schedules involving transactions T1 and T2 (a) Serial schedule A: T1 followed by T2 (b) Serial schedule B: T2 followed by T1 (c) Two nonserial schedules C and D with interleaving of operations

- Problem with serial schedules
 - Limit concurrency by prohibiting interleaving of operations
 - Unacceptable in practice
 - Solution: determine which schedules are equivalent to a serial schedule and allow those to occur
- Serializable schedule of n transactions
 - Equivalent to some serial schedule of same n transactions

- Conflict equivalence
 - Relative order of any two conflicting operations is the same in both schedules
- Serializable schedules
 - Schedule S is serializable if it is conflict equivalent to some serial schedule S'.

Testing for serializability of a schedule

- 1. For each transaction T_i participating in schedule S, create a node labeled T_i in the precedence graph.
- **2.** For each case in *S* where T_j executes a read_item(*X*) after T_i executes a write_item(*X*), create an edge ($T_i \rightarrow T_j$) in the precedence graph.
- **3.** For each case in S where T_j executes a write_item(X) after T_i executes a read_item(X), create an edge ($T_i \rightarrow T_j$) in the precedence graph.
- **4.** For each case in *S* where T_j executes a write_item(*X*) after T_i executes a write_item(*X*), create an edge $(T_i \rightarrow T_j)$ in the precedence graph.
- **5.** The schedule *S* is serializable if and only if the precedence graph has no cycles.

Algorithm 20.1 Testing conflict serializability of a schedule S

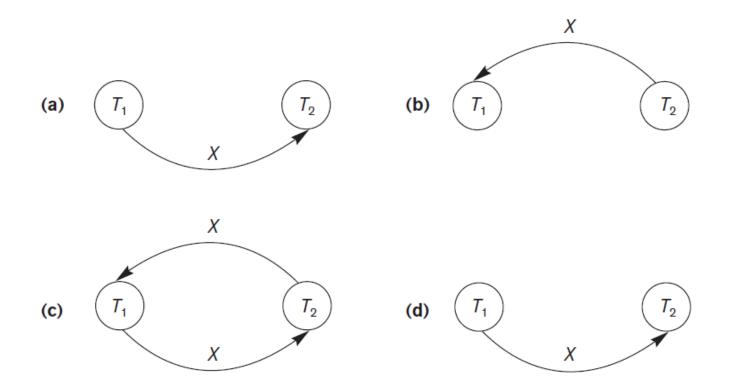

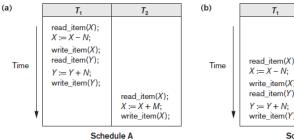

Figure 20.7 Constructing the precedence graphs for schedules A to D from Figure 20.5 to test for conflict serializability (a) Precedence graph for serial schedule A (b) Precedence graph for serial schedule B (c) Precedence graph for schedule C (not serializable) (d) Precedence graph for schedule D (serializable, equivalent to schedule A)

- 1. For each transaction T_i participating in schedule S, create a node labeled T_i in the precedence graph.
- **2.** For each case in S where T_i executes a read_item(X) after T_i executes a write_item(X), create an edge $(T_i \rightarrow T_j)$ in the precedence graph.
- 3. For each case in S where T_i executes a write_item(X) after T_i executes a read_item(X), create an edge $(T_i \to T_i)$ in the precedence graph.
- 4. For each case in S where T_i executes a write_item(X) after T_i executes a write_item(X), create an edge $(T_i \rightarrow T_j)$ in the precedence graph.
- **5.** The schedule *S* is serializable if and only if the precedence graph has no cycles.

Schedule D		

How Serializability is Used for Concurrency Control

- Being serializable is different from being serial
- Serializable schedule gives benefit of concurrent execution
 - Without giving up any correctness
- Difficult to test for serializability in practice
 - Factors such as system load, time of transaction submission, and process priority affect ordering of operations
- DBMS enforces protocols
 - Set of rules to ensure serializability

20.6 Transaction Support in SQL

- No explicit Begin_Transaction statement
- Every transaction must have an explicit end statement
 - COMMIT
 - ROLLBACK
- Access mode is READ ONLY or READ WRITE
- Diagnostic area size option
 - Integer value indicating number of conditions held simultaneously in the diagnostic area

20.7 Summary

- Single and multiuser database transactions
- Uncontrolled execution of concurrent transactions
- System log
- Failure recovery
- Committed transaction
- Schedule (history) defines execution sequence
 - Schedule recoverability
 - Schedule equivalence
- Serializability of schedules
